May 22, 2023

Given  $\{x_i, y_i\}_{i=1}^M$  and  $\{x_i\}_{i=M+1}^N$ , we predict  $y_i(x_i)$  for  $i = M + 1, \dots, N$  where  $M \ll N$ .

We construct our graphs by KNN or Proximity graph construction.

- General optimization

$$\vec{f}^* = \arg \min_{\vec{f} \in \mathbb{R}^m} \mathcal{L}(\vec{f}, y) + \lambda \vec{f}^T C^{-1} \vec{f}$$

where  $\mathcal{L}$  is a loss function:

- Probit loss

$$\mathcal{L}(\vec{f}, y) = - \sum_{j=1}^M \log \Psi(\vec{f}_j y_j)$$

- Regression loss

$$\mathcal{L}(\vec{f}, y) = \sum_{j=1}^M \left( \vec{f}_j - y_j \right)^2$$

- General optimization

$$\vec{f}^* = \arg \min_{\vec{f} \in \mathbb{R}^m} \mathcal{L}(\vec{f}, y) + \lambda \vec{f}^T C^{-1} \vec{f}$$

where  $C = (L + \tau^2 I)^{-\alpha}$ , where  $L$  is the graph Laplacian.

- $C$  embeds the spectral geometric information in our regression problem:

$$C = \tau^{-2\alpha} \sum_{q=1}^Q \mathbb{1}_{G_q} \mathbb{1}_{G_q}^T + O(1)$$

Using the K-Nearest Neighbors Graph with Uniform Weights

Loss Function	Classification Accuracy (over 50 trials)
Probit	100.0%
Regression	100.0%

# Results

## Three Cluster Case

Using the Proximity Graph with RBF Weights

Loss Function	Classification Accuracy (over 50 trials)
Probit	100.0%
Regression	100.0%

Using the K-Nearest Neighbors Graph with RBF Weights

Loss Function	Classification Accuracy (over 50 trials)
Probit	96.3%
Regression	95.8%

### Using the Proximity Graph with RBF Weights

Loss Function	Classification Accuracy (on 1 trial)
Probit	73.0%
Regression	63.0%

- Conclusions
  - For well separated clusters, the method is effective, even without careful tuning
  - Not the case for more difficult scenarios
- Challenges Encountered
  - Tuning of parameters - especially for real data
  - Majority labelling
- Next Steps
  - Plan to apply this approach to MNIST to test on real data
  - Anticipate tuning challenges for more difficult pairs of numbers
